Neural Nets and Language

Language

Discrete, structured (graphs, trees)

Neural-Nets

Continuous: poor native support for structure

Big challenge: writing code that translates between the {discrete-structured, continuous} regimes

Outline

- Computation graphs (general)
- Neural Nets in DyNet
- RNNs
- Minibatching
- New functions
- Tagging with BiLSTM
- Structured perceptron

Expression

 \vec{x}

graph:

Expression

 \vec{x}^{\top}

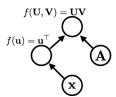

- Edge: function argument / data dependency
- A node with an incoming edge is a function $F \equiv f(u)$ edge's tail node
- A node computes its value and the value of its derivative w.r.t each argument (edge) times a derivative $\frac{\partial f}{\partial u}$

Expression

 $\vec{x}^{\top}A$

graph:

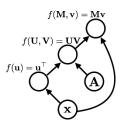

Functions can be nullary, unary, binary, ... n-ary. Often they are unary or binary.

Expression

 $\vec{x}^{\mathsf{T}} A x$

graph:

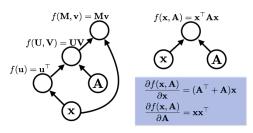

Computation graphs are (usually) directed and acyclic

Expression

$$\vec{x}^{\mathsf{T}} A x$$

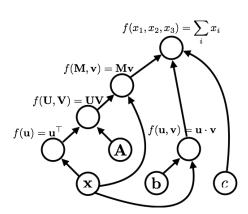

graph:

Expression

$$\vec{x}^{\mathsf{T}}Ax + b \cdot \vec{x} + c$$

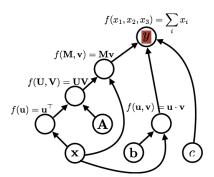

graph:

Expression

$$\mathbf{y} = \vec{\mathbf{x}}^{\mathsf{T}} A \mathbf{x} + \mathbf{b} \cdot \vec{\mathbf{x}} + \mathbf{c}$$

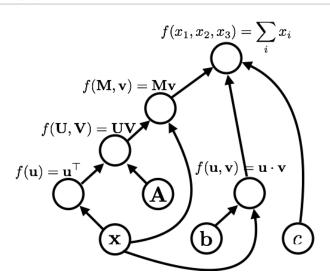

graph:

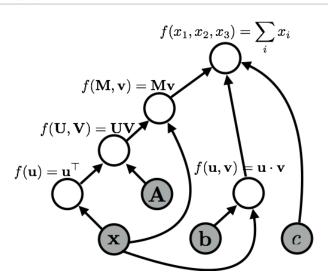

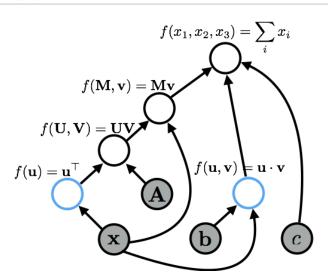

Variable names label nodes

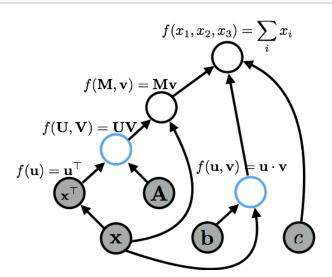

Algorithms

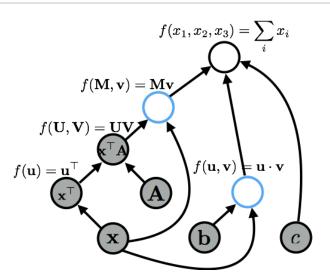

- Graph construction
- Forward propagation
 - Loop over nodes in topological order
 - Compute the value of the node given its inputs
 - Given my inputs, make a prediction (or compute an "error" with respect to a "target output")
- Backward propagation
 - Loop over the nodes in reverse topological order starting with a final goal node
 - Compute derivatives of final goal node value with respect to each edgeâĂŹs tail node
 - How does the output change if I make a small change to the inputs?

Constructing Graphs

Static declaration

- Define architecture, run data through
- PROS: Optimization, hardware support
- CONS: Structured data ugly, graph language

Torch, Theano, Tensorflow

Dynamic declaration

- Graph implicit with data
- PROS: Native language, interleave construction/evaluation
- CONS: Slower, computation can be wasted

Stan, Chainer, DyNet

Dynamic Hierarchy in Language

• Language is hierarchical

Dynamic Hierarchy in Language

Language is hierarchical

Phrases

Documents

This film was completely unbelievable.

The characters were wooden and the plot was absurd.

That being said, I liked it.

Dynamic Hierarchy in Language

- Language is hierarchical
 - Graph should reflect this reality
 - Traditional flow-control best for processing
- Combinatorial algorithms (e.g., dynamic programming)
- Exploit independencies to compute over a large space of operations tractably

· Before DyNet:

- AD libraries are fast and good, lack deep learning must-haves (GPUs, optimization algorithms, primitives for implementing RNNs, etc.)
- Deep learning toolkits don't support dynamic graphs well
- DyNet is a hybrid between a generic autodiff library and a Deep learning toolkit
 - It has the flexibility of a good AD library
 - It has most obligatory DL primitives¹
 - Useful for RL over structure (need this later)

¹Although the emphasis is dynamic operation, it can run perfectly well in "static mode". It's quite fast too! But if you're happy with that, probably stick to TensorFlow/Theano/Torch.

DyNet

- C++ backend based on Eigen (like TensorFlow)
- Custom ("quirky") memory management
- A few well-hidden assumptions make the graph construction and execution very fast.
- Thin Python wrapper on C++ API
